Body mass index and body image anxiety in a sample of undergraduate students

Pop Cristiana Lucretia

Abstract

Purpose: The study purpose is to estimate in which range the body image dissatisfaction affects the young women in our research group and to determine how objective these perceptions are. The main question this research raises is if the body image acceptance, which is a subjective variable is in a significant correlation with BMI as an objective parameter?

Material: This cross-sectional study was undertaken on a sample of 160 white female first-year undergraduate students, homogenous, with a mean age of 20.3 years (SD = 0.68), attending physical education classes. BMI and BDI were calculated on anthropometrical measurements and questionnaires.

Results: 79% of the questioned girls have difficulties in accepting their body image, even 87.7% of the subjects have been in normal and underweight category. A strong and significant correlation between BMI and BDI was found r=64 (p< .0005). 41% of body dissatisfaction index is determined by body mass index and subsequent by weight and fat deposits. Both these parameters could be improved through physical education means and a healthy lifestyle.

Conclusions: Summarizing the study results is acceptable to consider BMI values as useful predictors of body dissatisfaction risk among young female. Through physical education they gain confidence and positive body awareness alleviating anxiety related to physical appearance.

Keywords: physical appearance, health, well-being, physical education, weight management.

Introduction

The physical appearance is one of the first individual characteristics noticed by others and has an important impact in social interactions. Appearance in general and body image in particular have become very important constructs in contemporary Western societies [1]. Body image is not just a cognitive construct, but also a reflection of attitudes in interaction with others. The tendency to link physical attractiveness with positive personal qualities became a cultural stereotype not only in western culture, but globally also. The avalanche of perfect bodies in mass media, advertising and social media is an overburden for our subconscious, determining us to accept that “what is beautiful is good and desirable”; physical attractiveness being often linked with success.

In present times the personal physical image is a form of gaining a distinct place in the social environment and for achieving this status the investments in body appearance (cosmetics products and procedures, piercing and tattoos, plastic surgeries, sport materials and equipment, etc) are notably for both: women and men.

As they grow up children are building a picture or image of themselves. This image develops through the things that they can or cannot do and by how other people see them. Poor opinion of our body can cause low self esteem and self confidence, eating disorders and even depression. A recent study has concluded that 61.6% of adolescents with BID endorsed depressive symptoms [2]. An important contribution in constructing the youth’s body image has the media. Constantly watching ‘perfect’ bodies can feed their insecurities over attractiveness and weight. Studies show that idealized body image contributes to eating disorders as anorexia nervosa or bulimia, steroid use, protein supplements [3] and eventually plastic surgery.

During adolescence girls, more than boys, have particular concerns about weight, body shape and self image. There are scientific evidence that body image is experienced negatively by the majority of women and girls [4, 5]. Many are dissatisfied with their body size and weight because slimness is seen as the desirable standard and as the beauty pattern especially for young women. In adulthood also the underweight is much more prevalent among women compared with men [6].

Physical activity is of fundamental importance for maintaining the life functions and it is an essential part of having a healthy lifestyle. It has been proven that a certain level of physical activities has a protective role in the prophylaxis and development of cardiovascular disease, metabolic and skeletal disorders, and even mental illness [7]. Leisure and physical activity has been shown to be an effective intervention for improving body image and having beneficial emotional effects across all ages and both genders. In an extensive meta-analysis of 35 studies Reel and colleagues [8] examined the association between exercise and body concerns and the outcome was a medium overall size effect (ES=0.45 – 0.47). The authors concluded that exercise has a significant, positive effect on body image, body esteem and physical self concept. This statement is encouraging for PE teachers to design and deliver programs with this specific goal in mind: improving student’s body image for their physical and emotional well-being.
This study purpose is to estimate in which range the body image dissatisfaction affects the young women in our research group and to determine how objective these perceptions are. The main question this paper raises is if the body image acceptance, which is a subjective variable, is in a significant correlation with BMI as an objective parameter? Therefore I estimate the average BMI for 19-24 years old female student population and the share of different weight sub-groups in the study sample. In the discussion section a case was made out for exercise intervention on changing body image and overcoming young females anxiety related with physical appearance.

Materials and methods
This cross-sectional study was undertaken on a sample of 160 white female university students. The age of the participants ranged from 19 to 24 years; the mean age was 20.3 years (SD = 0.68) and the low coefficient of variance (CV=3.45%) demonstrate a high sample homogeneity.

The participants were randomly selected from those attending physical education classes in tertiary economic education. Therefore we assumed to have a healthy, cooperative, young women research sample with an urban lifestyle. The students’ inclusion in the research sample was voluntary agreed.

The measurements and questionnaire were applied in a context related with physical activities, health, fitness and body shape improvement.

The anthropometrical measurements – high and weight - enable us to calculate the Body Mass Index (BMI) as an objective reference data. We consider the participants on this study as young adults as time the height values for the sample we measured are definitive. The female growth speed trails off to zero at about 15 or 16 years. We preferred direct measurement against self-measurement bar and electronic weight scale. The and weigh in light sport equipment, barefooteed, using

Results
BMI is a measure of body fat based on height and weight, and the normal range is usually considered as 18.5 to 24.99 kg/cm², with anything over 25 considered overweight and over 30, obese. Values less than 18.5 kg/cm² are related with thin bodies or being underweight. In our research sample, the distribution of BMI (see Table 1) shows a prevalence of normal and low values (88.75%).

The BMI mean value - 20.93 kg/cm² (SD = 3.30) is equivalent with a slender figure, corresponding to an average high of 1.65 m (SD = 0.06) and an average weight of ~ 57 kg (56.99 kg; SD = 9.70).

However 79 % of the questioned girls have difficulties in accepting their body image, and the first reason they gave is weight (13% want to gain weight and 66% want to lose weight). Just 21% of subjects positively evaluate the shape and size of their body. The next table (Table 2) illustrates the distribution of body dissatisfaction answers relative to BMI:

More interesting is that 46% from subjects in the underweight group are not satisfied with their body size, willing to lose more weight. From the normal weight group just 13,125 % young women are pleased with their physical appearance. The mean value of body dissatisfaction index in our sample is BDI = -1.2 - considering that in average each young women reported body dissatisfaction (M=-1.2; SD= 1.4) is strongly correlated with BMI: r (158)= .64, p< .0005. Because r ≠ 0 the null hypothesis was rejected and the alternative hypothesis might be accepted.

Using descriptive statistics for each variable we analysed summaries about the sample and about the collected data. For the parce variables we calculated the Pearson correlation coefficient (r) and further we tested its statistical significance using the “t” test. Then we compared the “t” score figured for the actual correlation in the study, using the standard t table cutoffs (df = N-2).

Using the correlation coefficient values we calculated the coefficient of determination: $r^2$ - in order to determine the proportion of variance explained by one of the variables. We used graphical method to represent the gap between objective BMI data and subjective body image reported by respondents.
This results support physical activity, which has certain results in improving body shape and its functional efficiency.

Discussion

Comparing the BMI results with other studies on female samples in Europe we find similarities and differences. An extensive study on females aged between 18 and 34 years [6], in Sweden (n = 1967) returns a different distribution (see Table 3):

The prevalence of underweight decreases naturally with age, as time the percentage is growing in the overweight and obese section. There are similarities regarding the normal weight percentage.

In a recent study on a sample of 884 teenagers (M = 14, 29 years old, SD = 1,29), from Spain the average BMI for girls was 21,98, with average values of 1,59 m high and 56,09 kg weight [10]. Considering the age difference (from 14,29 to 20,3), and the lower BMI value, we consider the prevalence of normal weight and underweight in our sample as being confirmed.

We kept the BMI comparison in European geographical space and Caucasian racial typology because a study on female students of same age (M=19,99, SD=4,79) in USA returns significantly bigger values – M=24,52 kg/m² (SD=5,69), with approximately 30% of the sample maintaining a BMI of 25 or greater, indicating that they were overweight or obese [11].

Negative body image has usually been defined as dissatisfaction with one’s physical appearance. Body image dissatisfaction is a reality for a large share in our research sample. 79% of the young women questioned, wanted to change something on their body shape and size and eventually to lose weight. Even 87,7% of the subjects have been in normal and underweight category, most of them, 66% wanted to lose weight, for an ideal, slimmer silhouette. This data confirm the thesis that landmarks that society promotes are very severe for most girls and young women and put them in a position of inferiority, repercussions on self esteem and self confidence [12].

The following graph (see Fig. 1) reflects the difference between BMI values and the weight perception and how young women tend to distort their physical dimensions. In this research sample 66% of the girls had normal weight and 66% of them wanted to lose weight; while the BMI results had a normal distribution, the body dissatisfaction index (BDI) had an ascendant trend. This difference between the two trend lines represents the body image disturbed perception. In percentage it can be quantified in around 55% of subjects with normal weight, but perceiving their self body mostly too heavy.

Disturbed self perception is usually associated with preoccupation, insecure attitude or seeking reassurance in peer’s opinion. An explanation for this insecurity is the fashion industry’s controversial promotion of underweight models and unrealistic imagery, which in time created the Western cultural pattern. The question which arises is how could this postmodern society to overcome the twenty-first century frustration, depressions, anxieties and psychoses when natural beauty has been annulated by botox’s dictatorship [4], the cult of anorexia and emaciated super models?

An important part (41%) of body dissatisfaction is determined by body mass index and subsequent by weight and fat deposits. It means that body image can be enhanced in 41% with physical education means, being in know that the most commonly mentioned PE objective are improving the state of health and a harmonious physical development. Even body image acceptance is a subjective issue, depending on cultural and social factors, yet we find a consistent, statistical significant correlation with BMI (r (158) = 0.64, p< .0005). The explanation could consist in body composition representing the body fat and muscle mass ration. Fat tissue contains no water and is bigger in volume comparative with muscle tissue which has higher density [13]. A higher percentage of body fat increase the

overall body volume regardless the BMI values.

Summarizing the obtained data is acceptable to consider that BMI values could be useful predictors of body dissatisfaction risk among young female. Our conclusion are confirmed by others studies’ results investigating women samples, generally students, in divers cultural and ethnic regions. Jaworowska and Bazylak [14] have found in a sample of Polish female students almost the same percentage (65.6%) of body dissatisfaction. In Brazil women seems to be more indulgent with their appearance, whereas the prevalence of dissatisfaction reported was 47.3% [15]. Among a Pakistani students sample body dissatisfaction was complete: 45.6% of the respondents perceived their self body as too heavy, while 54.4% perceived it as too thin [16]. In a different cultural environment, in Saudi Arabia, among a group of young female students aged 21.02 (± 1.48 SD) with a BMI mean value of 22.79 (± 4.71 SD) 26.4% reported to be satisfied, 18.6% perceived self body as too thin, while 55% perceived as being too heavy and wanted to lose weight [17]. These results are close to the percentage obtained in our study: 21% satisfied, 13% wanted to gain weight and 66% wanted to lose weight.

There are scientific studies which are linking women’s body dissatisfaction and low self-esteem for physical appearance [13, 18]. This perception can have repercussions in lowering self-esteem for physical appearance especially around 20 years of age, when young women are still studying, but right before important life choices as a career or a life partner. A systematic review concluded that weight management and behavioral interventions could be successful by boosting self-esteem and increasing satisfaction with body areas too [19].

Practical interventions and scientific studies demonstrate without any doubt the potential positive effect for exercise to improve both physical and psychological well-being. In the psychological well-being category we can frame the perceptions, opinions and feelings related with body image, health condition, self esteem, etc, all of them improvable through physical exercise. Three different meta-analyses [20- 22] draw the same consistent conclusion: exercise has significant positive effects on body image. More interesting seems to be the mechanism that could moderate the effects of exercise on body image.

Changes in objective indices of physical fitness play a minor role in body image change, whereas improvements in perceived fitness and self-efficacy appear to be important mechanisms by which exercise improves body image. There is no direct correlation between objective progress in fitness level and the subjective perception of being fit or more functionally efficient [23]. The PE teacher can inspire students with self body acceptance and self confidence by shifting the focus away from appearance and emphasizing the physical and mental benefits of exercise. This study discloses the unbreakable relationship between mind and body, meaning that every intervention at physical level will have effects on emotional and physical well-being too. This holistic approach offers us a subtle instrument for changing mentalities and attitudes in addition to physical skills and abilities [12].

The exercise intervention on changing body image depends on frequency and intensity of training [24]. The changes in body image are positively when the exercise are performed on more days per week and at least at a moderate intensity. Aerobic exercise, strength-training, and combined aerobic/strength-training interventions are equally effective. The type of exercise depends more on preferences and personal goals. A sensitive task for a teacher dealing with students with a low self image...
acceptance is to help them to set realistic and achievable goals through appropriate exercise.

The satisfaction gained from exercising can eventually become an intrinsic motivation, especially when the practitioner internalizes the idea that effort has positive effects on enhancing perceptions about body shape and self-image.

Conclusions

Regarding subjective young women’s body image perception we conclude that it surpass the normal anthropometrical references regarding average body mass. Under the social and cultural patterns pressure a majority of women are not satisfied with their body shape regardless the BMI values and identify their ideal body with a thinner version. Even underweight persons are willing to lose weight in order to correspond to an expected physical attractiveness standard. The normality for female students around 20 years of age seems to be a constant preoccupation for losing weight and an ultrathin body is their beauty ideal.

41% of body dissatisfaction index is determined by body mass index and subsequent by weight and fat deposits. Both these parameters could be improved through physical and health education. An increased number of adequate physical activities, spending time outdoors, a healthy lifestyle or cutting out unhealthy foods are a few steps to take for increasing the female student’s physical tonus and could offer an alternative to this eternal and quasi-globalised body dissatisfaction.

Using just one parameter for estimating body fat is a limitation of this study. There is a credible possibility that other measurements as body composition, waist – hip ratio or height – waist ratio in relation with body dissatisfaction in young women sample to return different result.

Conflict of interests

The author declares that there is no conflict of interest.
